Abstract

Background: Cervical cancer is the fourth most deadly cancer in the world, and it is caused by infection of high-risk subtypes of Human PapillomaVirus (HPV) in most cases. The aims of this study were to determine the prevalence oncogenic HPV in cervical cancer patients in Riau Province Indonesia and to determine the clinical manifestation of HPV in cervical cancer patients in Riau Province Indonesia.

Methods: This research was a descriptive study conducted at Arifin Achmad General Hospital Riau from February to August 2018 which aimed to analyze HPV genotype prevalence oncogenic of cervical cancer patients.

Results: This study showed out 86 of 110 women (78.1%) were found HPV positive, and the most common genotype of HPV was HPV 16 (38.2%). The average age of cervical cancer patient was 50 years old, and the average number of parities was 4 times. The majority of participants were married at the age before 20 years (77.3%) and had low educational background (64.5%). Vaginal bleeding happened in more than half of the participant as major clinical manifestation (72.7%), followed by fluor albus (72.7%), pelvic pain (60.2%) and fatigue (65.9%).

Conclusions: The most common HPV genotype in Riau Province was HPV type 16 and the most common clinical symptoms of cervical cancer patient were vaginal bleeding, fluor albus, pelvic pain and fatigue.

Keywords: Cervical cancer, Clinical manifestations Human Papilomavirus, Human Papilomavirus genotype prevalence.

Introduction

Cervical cancer is the fourth most malignancies of women in the world. Concerning the epidemiology, it is estimated that there are 569.847 new cases and 311.365 deaths in 2012 (1). If the number of cases continues to increase, it is estimated that by 2025 cervical cancer in the world will reach 20 million new cases (2). The main risk factor for cervical cancer is

related to Human Papilloma Virus (HPV) infection in the cervical epithelium (3). The incidence of recurrence and metastasis to other organs is still the main cause of cervical cancer death, although cervical cancer can be cured at an early stage through surgery and chemotherapy (4).

Human Papillomavirus genotypes are sorted

based on their findings. Alpha-papillomavirus (including all genital papillomaviruses), Beta-papillomavirus (which is responsible for epidermo dysplasia verruciformis), and Gamma-papillomaviruses (which are responsible for skin lesions) are three generations of papillomaviridae responsible for significant diseases in humans (5).

It is estimated that 5% of cancers in humans are caused by Human Papilloma Virus (HPV) infections. Type 16 HPV is a major cause of cervical cancer, with percentage, respectively, 45.5% in worldwide and 60% in Indonesia (6). It is reported that 70% of cervical cancer caused by the infection of oncogenic type of HPV (high risk type) and it is associated with anogenital cancers in men and women, such as cancer of the penis, vulva, vagina, anal, and oropharyngeal cancer (7). Approximately there are 100 different subtypes of HPV with different variations in potency and oncogenic, and which specifically infecting anogenital area are types 16, 18, 31, 33, 35, 39, 45, 52, 52, 56, 58, 66, and 69 HPV (8).

In study with cervical cancer samples, 99.7% of cases had deoxyribonucleid acid (DNA) HPV and dominated by high-risk types, namely 16, 18, 31, and 45, this indicates that high-risk HPV plays a role in the development of cervical cancer (9).

Generally, women with adenocarcinoma and adenosquamous carcinoma are HPV type 18, different from HPV type 16 in women with squamous cell carcinoma. To reduce the incidence of cervical cancer in younger women, HPV testing and vaccination can help, especially adenocarcinoma and adenosquamous carcinoma (10).

Several studies have led to the development of vaccines that offer protection against HPV infections. In early stages, cervical cancer is mostly asymptomatic and might be under diagnosed. Late symptoms include abnormal vaginal bleeding, post-coital bleeding, vaginal discharge be likely the most common complaint that makes patient come to medical workers (11). In this study, we aim to analyze HPV genotype prevalence and describe clinical presentation of cervical cancer patient in Riau.

Materials and Methods

This research was a descriptive design study that analyzed HPV genotypes and clinical presentation of cervical cancer patients conducted from February 2018 to August 2018. The research permit was granted by the ethics committee of the medical faculty of Universitas Riau with the number 089/UN.19.5.1.1.8/UEPKK/2018. An informed written consent was taken from each participant.

In this study, total 110 participants visiting gynecology department at Arifin Achmad General Hospital Riau Province were recruited consecutively, means all subjects who met the inclusion and exclusion criteria were taken as samples. This method was selected because it was not possible to collect large samples at once. The exclusion criteria in the study were inadequate amount and quality of cervical tissue. While the inclusion criteria were women diagnosed or suspected cervical cancer according to physical examination or histopathology, cervical tissue can be taken as a sample and willing to participate in the study by signing informed consent sheet.

Participants who were enrolled in this study were asked to fill out a questionnaire containing questions about identity/characteristics of patients, clinical complaints and examinations that have been undertaken. Hence, each participant's cervical tissues were taken as a sample for further laboratory tests. DNA is extracted from cervical tissue biopsies with a biopsy punch technique then DNA is extracted from cervical tissue biopsies using purelink Genomic DNA isolation kits (Invitrogen). The working procedure is in accordance with the protocol recommended by the manufacturer.

HPV detection was carried out using DNA amplification. MY/GP primer used is cgtccacaagagggaataactgac for forward and gcaccagggatcataactaatgg for reverse. The total volume of PCR mixture is 50 ml consisting of 0.5 to 20.0 ml of DNA, 50 mM Tris-HCl (pH 8.4), 10 mM KCl, 2.0 mM MgCl₂ 1% b-mercaptoethanol, 0.05% bovine serum albumin, 0.2 mM (each) deoxynucleoside triphosphate, 20 pmol from each primer, and 2.5

U of Taq polymerase (Boehringer Mannheim). The PCR program consists of 94 °C for 5 min, followed by 40 amplification cycles consisting of 94 °C for 30s, 45 °C for 60s, and 72 °C for 60s and ending with a final 72 °C extension for 10 minutes. PCR products measuring 450 bp were analyzed using electrophoresis gel agarose 1%. Then HPV (Roche diagnostic) Probe Array (LPA) line was used to identify HPV genotype.

Results

Identification of HPV is done using the universal MY / GP primer, then a positive sample of HPV will produce a DNA tape size of 150 bp on agarose gel. The results of HPV DNA isolation can be seen in Figure 1.

Data prevalence research samples from a total of 110 samples found 86 cases with positive HPV and 24 cases with negative HPV, or 78.2% HPV positive and 21.8% HPV negative.

The results of genotype analysis using specific primer to high-risk HPV, namely type 16, 18, 45, 52, 31 and 33, showed the distribution of HPV type 16 most of 42 cases (48.8%), followed by HPV type 18 as many as 9 cases (10.5%). Mixed types were found in 11 cases (12.8%). No types 31 and 33 were found, as well as 23 cases (26.7%) cannot be identified by type. The distribution data of HPV genotypes analysis can be seen in Figure 2.

Fig. 1. Identify HPV DNA with my/GP universal primer with a 150 bp DNA band. (A positive sample of HPV will produce a DNA tape size of 150 bp on agarose gel.)

Fig. 2. Distribution of HPV in cervical cancer patients based on genotype analysis. Distribution of HPV type 16 most of cases (48.8%), followed by HPV type 18 cases, and mixed types.

Table 1 provides a distribution overview of samples characteristics in this study. Based on this table, it can be concluded that the average patient belonged to the age group of the early elderly. Most of the patient's parity status is multiparity. Meanwhile, only a small proportion of patients have other risk factors for cervical cancer such as multi-partner sex, smoking history, and IUD use.

Clinical manifestations were obtained from

questionnaires that had been distributed to the participants when they were visiting Department of Obstetrics and Gynecology. The participants filled out a list of clinical manifestations that were felt when they came to the hospital. The distribution of clinical manifestations can be seen in Table 2. Based on table 2, the symptoms most frequently complained by all patients in this study were vaginal bleeding, fluor albus, fatigue and pelvic pain.

Table 1. Characteristics of subjects.

Variable	Mean \pm SD	N (%)
Age (years)	50 \pm 9.28	
Parity	4.2 \pm 2.6	
Educational status		
• Elementary School – Junior High School		71(64.5%)
• \geq Senior High School		39(35.5%)
Length of marriage		
• <15 years		14(12.8%)
• 15 – 20 years		71(64.5%)
• >20 years		25(22.7%)
Sex partner (>1 person)		16(14.5%)
History of smoking		14(12.5%)
IUD (Intra Uterine Device)		16(14.8%)

Table 2. Clinical manifestation of the subjects.

Description	N(%)
Vaginal bleeding	80(72.7%)
Post coitus hemorrhage	52(47.1%)
Post menopause hemorrhage	48(43.2%)
<i>Fluor Albus</i>	80(72.7%)
Pelvic pain	66(60.2%)
Back pain	50(45.5%)
Fatigue	72(65.9%)
Leg pain	28(25.5%)
Decreased appetite	43(39.1%)
Limb edema	9(8.2%)
Urine/stool leakage	5(4.5%)

Discussion

The results showed 86 samples were HPV positive while 24 samples were negative. The results of genotype analysis are the highest distribution of HPV type 16 in 42 cases followed by HPV type 18 in 9 cases and HPV type 45. These results are consistent with research in Manado. HPV type 16 ranks first as the most common cause of cervical cancer with a percentage of 76.36% (12). Langheden, 2018 found that most HPV cases are dominated by HPV type 16 by 60%, followed by HPV18 by 19%, and other types total below 10% (13). Different results obtained by Zhang, where the most prevalent type was HPV-52 by 2,04% followed by HPV-16 by 1,81% (14).

Similar results were obtained by Awua who examined 256 patients with cervical cancer. A total of 230 patients were proven to have positive HPV with the types found were HPV18 (47.4%), HPV59 (42.2%), HPV45 (37.4%) and HPV16 (9.0%) (15). Volpini also detected variations in the type of high risk HPV with the highest prevalence being in HPV types 16 (8.9%) followed by HPV types 45 and 18 with values of 6.7% and 4.4% (16).

The results of this study show that the average patient belonged to the age group of the early elderly. The same results were obtained from studies conducted in Turkey by Boyraz on 126 cervical cancer patients with an average age of 52 years in the range of 29-83 years (17). But it is different from studies conducted on 524 women in Puerto Rico, where the most age is less than 35 years (18).

The level of education is closely related to public awareness to get treatment from medical personnel. The results showed the majority of patients with low education, one level below senior high school. The level of education also affects personal hygiene behavior. This is in line with systematic review research by Lim, J in Sub Saharan Africa states that poor knowledge of cervical cancer becomes a major personal obstacle to cervical screening and becomes an obstacle for women to prevent cervical cancer (19).

In this study it was seen that women who have sexual relations under 20 years are quite

dominant in relation to cervical cancer. Research conducted by Mitiku found that the incidence of cervical cancer is strongly associated with sexual behavior, such as multiple sexual partners and age during sexual intercourse. The risk of suffering from cervical cancer increases more than 6 times in women who have sexual contact at the age of < 20 years {Formatting Citation}. In this study, the average woman gave birth 4 times, with a range of 2-6 times.

Another study conducted by Setyarini found that women with > 3 times parital status have 5 times risk of suffering from cervical cancer (21). Parity is an extrinsic factor that is closely related to an increased risk of cervical cancer. Let alone, if the time interval between labor is too close. The possible connection is that hormonal factors during pregnancy that facilitate the development of cancer cells. In pregnant women, there will be a process of uterine cervical cell metaplasia and low immune power of pregnant women due to the process during childbirth. But women with parity 0 and parity > 5 also have cervical cancer. This indicates that parity is not the only cause of cervical cancer {Formatting Citation}.

In 2015, Liu Chang conducted an analysis that looked at the correlation between multiple sexual partners and the incidence of cervical cancer. The results showed that women who had 4-7 sexual partners had a risk of developing cervical cancer whether or not the HPV virus was detected (23). The incidence of cervical cancer is associated with transmission from men (24).

In this study, showed that 16 patients had more than 1 sexual partners. This was probably due to the culture of Indonesian people who still considered changing partners as an act that violated the norms in society. Other risk factors derived from this study were smoking history and IUD use. Research by Zidi et al says that smoking is the most significant environmental risk factor for cervical cancer. It is associated with the chemical carcinogen benzopyrene contained in cigarettes is shown

to increase the synthesis of HPV in cervical cells and cause viral persistence in many cases (25). Other studies said that long-term hormonal use with CIN 2/3 cervical cancer risk has a positive relationship (26).

Based on the results, one of the symptoms most frequently complained by all patients in this study is vaginal bleeding. Vaginal bleeding is the cause of death by 6% in cases of cervical cancer. The incidence varies from 0.7% - 100% and the treatment faces many challenges (27).

Other symptoms like weight loss, fatigue, and lack of appetite are common symptoms experienced by cancer patients, including cervical cancer.

The presence of fistulas in the form of leaking urine / feces is a rare form of complications from the course of cervical cancer. This fistula if left unchecked will cause a continuous discharge of fluid from the vagina. Surgery is the most effective option for repairing the fistula. In some cases, treatment also includes giving a cream or ointment to reduce fluid coming out of the vagina and prevent irritation and tissue damage to the vagina and surrounding tissue. There were also

about 4.5% of patients in this study who experienced leakage of urine / feces.

This study shows out of 110 women, 86 (78.1%) were found HPV positive, and the most common HPV genotype in Pekanbaru is HPV type 16 (48.8%). Besides that, the most common clinical symptoms of cervical cancer patient are vaginal bleeding, fluor albus, pelvic pain and fatigue.
